## **CODE OF PRACTICE FOR WEED CONTROL TO PREVENT AND REDUCE PYRROLIZIDINE ALKALOID CONTAMINATION IN FOOD AND FEED**

**CAC/RCP 74-2014**

## 1. INTRODUCTION

Pyrrolizidine alkaloids (PAs) are natural toxins occurring in a wide variety of plants. Over 6 000 plant species throughout the world are expected to contain PAs. PAs are probably the most widely distributed natural toxins that can affect wildlife, livestock and humans.

PAs have a common toxicity profile with the liver being the main target organ of toxicity. Major signs of toxicity in all animal species include various degrees of progressive liver damage (centrilobular hepatocellular necrosis), and veno-occlusive disease. Furthermore, the International Agency for Research on Cancer (IARC) has classified three PAs, lasiocarpine, monocrotaline and riddelliine, as 'possibly carcinogenic to humans' (Group 2B). PAs may differ in potency, the relative potencies are currently not known due to lack of oral toxicity data on individual PAs, which hampers risk assessment for PAs.

Risks to humans may arise from the intake of PA contaminated food of vegetable or animal origin and outbreaks of toxicity in farm animals cause economic losses to farmers and rural communities. Direct human cases of poisoning via food are well-documented, which in some cases have resulted in deaths. Also, consumption of grain or grain products (flour or bread) contaminated with PA-containing seeds has caused outbreaks of poisoning. Further, plant parts which contain PAs have been identified in foods prepared from agricultural crops, i.e. salad leaves. PAs were also found in products from animal origin, i.e. milk and eggs, indicating transfer of PAs from feed to edible tissues.

Although there are gaps in the information available on the toxicity and relative potency of individual PAs, and the contribution of different foods to overall exposure, dietary exposure to PAs should be as low as possible due to the potential health-threatening effects that can be caused by ingestion of these toxins via feed or food. To achieve this, management practices aimed at the prevention and reduction of contamination of food and feed with PAs must be undertaken.

Management practices to prevent or reduce PA contamination of food and feed can comprise weed management (removal/reduction) practices to reduce exposure of food-producing animals, including livestock and bees, to PA-containing plants, and practices to reduce presence of PAs in raw and processed commodities. This Code of Practice focuses on weed control. Deliberate use of PA-containing plants for foods and feed cannot be justified for any reason without appropriate assessment.

It should be emphasised that total eradication of PA-containing plants is not feasible or ecologically desirable. Also, grazing animals usually avoid eating most growing plant species containing PAs under normal circumstances. Generally, livestock graze on PA-containing plants when feed gets scarce in conditions of drought or on over-grazed pastures. Livestock may also consume PA-containing plants when they are present in dried form in feed. Therefore, good feeding practice is important besides management through weed control.

## 2. OBJECTIVE

This Code of Practice aims to provide good management practices for weed control of PA-containing plants to prevent and reduce the contamination of food and feed with PAs. In this regard, this code will cover control measures for the management of the PA-containing plant as well as measures for control of plant release and spread.

## 3. SCOPE

The scope of this Code of Practice is to provide guidance to prevent contamination of food and feed with PAs on the one hand and, where contamination cannot be completely avoided, to reduce the PA contamination in food and feed by weed control. This Code of Practice should be read in conjunction with other relevant Codes of Practice for the prevention and reduction of other contaminants in food and feed.

## 4. EVALUATION OF COMPLIANCE WITH RELEVANT LEGISLATION

All management practices presented in this Code of Practice shall be followed in compliance with relevant national or international legislation and standards, including general requirement for consumer and worker protection.

## 5. LIMITATIONS

It should be recognised that the implementation of the management measures described in this Code of Practice may be difficult in a number of countries. This may be either due to lack of knowledge or resources or due to geographical, environmental or practical limitations, such as the area of land being too large, or inaccessibility of certain regions for agricultural machinery. The measures described in this Code of Practice serve therefore as guidance and each measure described in this Code of Practice should be assessed by national authorities or other professional and advisory bodies to ensure that it is appropriate and practical for their country-specific conditions.

There is currently insufficient information concerning the effectiveness of the various management measures and therefore no full evaluation of the management measures can be conducted. When such information becomes available, an evaluation of the effectiveness of the proposed management measures would be helpful in identifying the most appropriate combination of practices for management of PA-containing plants thereby lowering the chance of PA-contamination of food and feed.

## 6. GENERAL PRINCIPLES FOR WEED CONTROL OF PA-CONTAINING PLANTS

To ensure adequate prevention of the spread of PA-containing plants, and to lower the costs of control measures, early detection and identification of these plants is essential followed by action to prevent contamination of food and feed.

To achieve an early detection, raising awareness by providing good information to the farmers and local population (including contractors and roadside maintenance staff) is critical. Information could be provided by using materials such as leaflets and website information with an overview and description of the most important PA-containing plants, their ecology, the need to proceed to action and how/where. In this respect, it is important to adapt the type of recommendations to the situation of the person involved, i.e. private persons keeping horses, sheep etc. on a small piece of land need other instructions than professional farmers. Communication with relevant national and local government organisations should also take place.

Once PA-containing plants are detected, if suitable data are available, the risks for human and animal health must be established in order to identify the need for an integrated weed management plan. In this respect, it must be recognised that the different PA-containing plants may react in a different way to a particular management measure. Therefore, it is always important to keep the ecology of the specific plant in mind. Additionally, influences of weather or climate must be taken into account. When seeking to prevent the spread of the PA-containing plants, all landowners, occupiers and managers must take a collective responsibility to ensure that effective control of the spread is achieved.

## 7. EVALUATION OF THE NEED TO PROCEED TO ACTION

Before considering any action, the need to proceed to action should be established by identifying the risks posed by the presence of PA-containing plants. This could be done by setting up a tiered risk characterisation approach based on:

- toxicity of the particular PAs, if known, present in the plant;
- the relevant contributions of the various PA-containing plants to the specific or total PA intake of the livestock or presence in food/feed, if known;
- proximity of the PA-containing plants to arable fields and meadows/pastures/grasslands;
- level of infestation;
- local circumstances;
- climate;
- soil type; and
- vegetation cover of receiving land.

The likelihood of PA-containing plants spreading to land used for agricultural practices or grazing and/or feed/forage production should be the determining factor for assessment of the risk.

As an example, principles for assessing and managing the risk posed to livestock by ragwort (*Jacobaea vulgaris*), a common PA-containing plant, have been identified. These have been based on practical considerations of the proximity of the ragwort to pastures for livestock (bullet 3 above):

- high risk: ragwort is present and flowering/seeding within 50 m of land used for grazing by food-producing animals or land used for feed/forage production;
- medium risk: ragwort is present within 50 m to 100 m of land used for grazing by food-producing animals or land used for feed/forage production;
- low risk: the land on which ragwort is present is more than 100 m from land used for grazing by food-producing animals or land used for feed/forage production.

In the example of ragwort control, when a “high risk” situation is identified, the guidance is that immediate action should be taken to control the spread of PA-containing plants using appropriate control techniques taking account of the status of the land. In case of a medium risk, a control policy may be established to ensure that when the situation changes from a medium to a high risk of spread, it is identified and dealt with in a timely manner using appropriate control techniques taking account of the status of the land. In case of a low risk, no immediate action is required.

Similar risk assessments and resulting actions could be carried out for other PA-containing plants, but noting that defining risk zones and appropriate actions in other situations, will require the different ecology of the relevant PA-containing plants to be taken into account alongside the bullets in paragraph 16.

## **8. RECOMMENDED PRACTICES**

### **8.1 Management of the presence of PA-containing plants**

For managing the presence of PA-containing plants, preferably a combination of non-chemical and chemical methods, i.e. integrated weed management, should be applied to obtain the most effective results.

The use of an integrated weed management plan could reduce the use of and reliance on herbicides, thereby lowering the chance of herbicide resistance, and allows weed management in most environments. However, it should be noted that in those cases where appropriate herbicides are available, their application alone could be sufficiently effective to manage weed presence.

Furthermore, an integrated weed management plan should be accompanied with practices to reduce the spread of PA-containing plants thereby preventing infestations to spread.

It should be kept in mind for the management practices described in this section that their application should not result in harmful consequences for agriculture, the livestock or the pasture. Some methods may be destructive for other plant species (such as the crop) as well as to the target species. Applying these methods must be directed to the eradication of individual plants and done after good planning taking into account possible risks to the environment.

#### **8.1.1 Mechanical methods**

PA-containing plants can be controlled by mechanical methods such as pulling, ploughing, milling and slashing. The timing of applying mechanical methods is important. These practices are best applied before flowering of the PA-containing plants to prevent seed production and seed spread. When handling the PA-containing plants, suitable precautions should be taken to protect operators' skin (contact with some plants might cause an allergic reaction) and prevent inhalation of pollen.

Effective manual control requires removal of the root crown and all larger roots. Therefore, manual control may only be effective for seedlings and young rosettes in contrast to bigger plants, which normally develop deep roots. In addition, effective hand pulling is useful for small infestations but is not cost-effective for large ones, nor is it suitable for large areas of land. In case of hand pulling, the plants should be handled and transported in a manner that prevents their spread, e.g. in hermetically sealed bags, and destroyed (burned) afterwards. It should be noted that disturbance of the soil may lead to more germination since buried seeds will be exposed to (sun) light.

#### **8.1.2 Chemical methods**

When applied carefully at the recommended dose of the herbicide, chemical spraying with appropriate herbicides may be an effective way of controlling PA-containing plants. Herbicides used should be registered for application in that specific situation. Also, herbicides should preferably be used in combination with other control methods to increase their effectiveness. The choice of herbicide depends on the specific PA-containing plant species and availability of appropriate herbicides.

For most PA-containing plants, in general the most effective time to spray herbicides is when the plants are actively growing and commencing flowering, i.e. in the spring before bloom and in the autumn applied to the new rosettes. Some herbicides require other timing due to their mode of action. PA-containing plants should not be sprayed when the plants are stressed either through lack of water, too much water, disease, insect or mechanical damage, as spray effectiveness will diminish.

The use of non-selective herbicides may damage the crop species and surrounding crops, pastures and environment. Hence, it is better to use selective herbicides or limit the use of non-selective herbicides for spray topping the PA-containing plant. Further, some PA-containing plants may develop resistance against a particular herbicide over time. It should be ensured that active substances are registered for the specific purpose in each country. In addition, as these substances are herbicides they may still have an inhibiting effect on crops, so care should be taken in case of possible bordering arable land.

In case of established PA-containing perennial plants, it is better to use systemic herbicides. Systemic herbicides are absorbed either by roots or foliar parts of a plant and are then translocated within the plant system to tissues that may be remote from the point of application.

In addition, care should be taken that herbicides are applied in suitable weather conditions, since the effective concentration of herbicides could be reduced when applied in unfavourable weather conditions, such as rain falls within 5 hours of application.

### 8.1.3 *Biological methods*

Natural enemies of a plant may be used to control PA-containing plants. It may be an economical and effective method. However, efficacy must have been established and the natural enemy must not present an environmental problem itself.

Tansy ragwort (*Jacobaea vulgaris*) densities may for example be reduced by the natural enemies *Longitarsus jacobaeae* (ragwort flea beetle) and a combination of *Longitarsus jacobaeae* and *Tyria jacobaeae* (cinnabar moth). Also *Cochylis atricapitana*, a ragwort stem and crown boring moth from Europe, was found to reduce the plant height of flowering plants and reduced the size and survival of rosettes. Another biocontrol agent used is *Platyptillia isodactyla* (ragwort plume moth) which has as common host marsh ragwort (*Senecio aquaticus*). *Deuterocampta quadrijuga* (blue heliotrope leaf-beetle) can completely defoliate blue heliotrope (*Heliotropium amplexicaule*), with both the larvae and adults feeding on the leaves.

However, good bio control is only feasible for a limited number of species as costs associated with finding, screening and testing potential agents can be very high. As such, successful biological control requires extensive development and establishment phases and costs. For most of the PA-containing plants no effective biological control agent is available. Research has shown that these methods are generally only very effective in the case of non-native plants.

### 8.1.4 *Other methods*

Soil solarisation, flaming (burning) and use of boiling water are other controlling methods that may be used for small infestations.

As there is some evidence that changing soil moisture and nutrient availability may influence the PA content of the roots, leaves and flowers of PA-containing plants, cultivation methods may change the PA content of remaining plants. For example, increasing soil moisture will lead to higher PA-concentrations in the roots. PA concentrations are expected to be higher when nutrient availability is low, i.e. higher concentrations were found in plants grown in sand without nutrients than with nutrients. It is, however, not clear whether the same effect may be expected in flowering plants.

Do not transport PA-containing plants unnecessarily and only when stored in hermetically sealed bags or containers.

Not all management practices are suitable to be used on every type of land. Therefore, specific management practices to control PA-containing plants are discussed separately hereafter specified by type of land: arable fields, pastures, and areas bordering the crop or pasture.

### 8.1.5 *Arable fields*

In the case of crops, the best timing of applying mechanical methods is at the start of crop growth. Once the crops are dense, weeds have little chance to grow. In crops such as wheat and millet etc., fields should be weeded prior to planting and periodically during the first six weeks of the growth cycle. A final weeding, about two weeks before harvest, if feasible, could reduce the possibility of contamination of the harvest with toxic plant parts significantly. In fact, in legume crops, mechanical or manual weeding may be the only option if infestation is large. Attention should be paid to areas bordering the crop, as these may constitute a continuous reservoir for the weed infestation.

### 8.1.6 *Pastures and areas bordering the crop or pasture*

Landowners are generally not legally responsible for the areas bordering the crop or pasture, such as road verges, sides of a ditch and ruderal places. Therefore, for this type of land it is extremely important that all landowners, occupiers and managers take a collective responsibility to ensure that effective control of possible spread of PA containing plants is achieved.

For large-scale restorations in pastures, mowing and cutting can be more easily applied. Cutting or slashing tansy ragwort (*Jacobaea vulgaris*) at the start or end of anthesis will reduce the number of flower heads. Therefore, it is recommended to do the first mowing when half of the plants start anthesis, and the second mowing when half of the re-established plants start anthesis again. On the other hand, fireweed (*Senecio madagascariensis*) should not be slashed in late spring or when more than 25% of the plants are flowering, as the mature plant, that otherwise might have died, may begin re-shooting. However, these mechanical methods

are not always effective in killing the plants and may even encourage them to re-shoot as is observed with tansy ragwort (*Jacobaea vulgaris*) and Paterson's curse (*Echium plantagineum*). As a consequence, slashing or mowing may need to be executed on a very regular basis and be applied in combination with other control measures as part of an integrated weed management plan. For example, high mowing frequencies can be combined with the use of additional nitrogen that will lead to the promotion of fast growing grass species which will impair the germination and establishment of PA-containing plants.

Attention should be paid to areas bordering the pasture, as these may constitute a continuous reservoir for the weed infestation.

In pastures, PA-resistant livestock can be quite effectively used in grazing management to reduce PA-containing plants since it may weaken the plants and prevent prolific seeding. Antimethanogenic therapy with bacteria may be used to increase ruminant resistance to PA toxicity. Animals with no previous exposure to PAs are very susceptible to poisoning while animals with prior exposure to PA-containing plants show enhanced rumen detoxifying activity. The bacterium *Peptostreptococcus heliotrinreducans* most likely plays an important role in this process.

In addition, preferably non-food producing animals should be used as PAs may transfer from feed into milk and edible tissues. The best livestock to use are sheep, especially non-pregnant, non-food producing Merino sheep, or goats. If food-producing animals are used, the edible products could potentially contain high levels of PAs, and as a precautionary approach, these edible products must be segregated and not sold for human consumption until it is confirmed that they do not contain PAs. When removing animals from affected areas it is necessary to avoid transfer of seeds on their hooves, coats and digestive tracts, which can infest a new area. That is, livestock can spread seeds by consuming and passing viable seeds through their digestive tract. The seeds that survive the digestive tract are eliminated in the manure, which is rich in nutrients that can increase weed emergence. Thus, for some weed species it may be appropriate to prevent animal grazing when the plants are setting seeds, or the spreading of seeds by livestock can be prevented by placing them into quarantine. Grazing management can be applied on low-level, widespread infestations. However, significant numbers of grazing animals must be available; water and fencing or herding to control movement must be set up and the timing, intensity and duration of grazing must be closely monitored and managed to prevent overgrazing. It must be recognised that overgrazing may lead to loss of the competitive nature of the pasture or of native plants, allowing PA-containing plants to return and spread over the bare soil, which could result in livestock poisoning. Hence, it is recommended to stop grazing during flowering of (a number of) PA-containing plants as their PA-production is then very high.

## **8.2 Control of plant release and spread**

### **8.2.1 Identify alternative plant sources to reduce undesirable growth**

For crops, sound crop rotations can also minimise weed problems, since it will help to build up soil fertility and structure to produce increasing yields. Increased fertility in its turn will reduce the impact of weeds, and rotating crops can reduce the seeding and germination of weeds. In pastures and areas bordering the crop or pasture, use alternative plant sources to reduce undesirable growth, i.e. by planting vigorous perennials that will suppress the introduction and growth of PA-containing plants. This can be achieved by 1) sowing winter pasture species; 2) allowing a stand over of summer pasture feed; and 3) growing combinations of winter and summer pastures. Pasture management must also often go along with other forms of weed control, such as herbicides and mechanical means. This should be done in accordance with Good Agricultural Practice, such as appropriate sowing time and depth, adequate fertility and moisture at sowing, which is important to ensure good pasture management. Furthermore, it is recommended to use agricultural methods such as water and nutrient management or mulching. The plant material used for mulching must be free of PA-plants and their seeds.

### **8.2.2 Control movement of plants/seeds over agricultural zones and pastures**

Assure planting of high quality, weed-free crops and weed-free grass seeds. When possible by national or regional laws and directives, use seed for planting that is not contaminated (e.g. certified seed).

### **8.2.3 Control plant seed movement on vehicles and agricultural machinery**

Clean vehicles, machinery and equipment that are used in infested areas to prevent introduction of the PA-containing plant to pastures or other agricultural land by spread of seeds. Weed-free buffer zones between infested and un-infested lands will help to contain any infestation.

### **8.2.4 Control plant seed movement on animals**

In case that livestock has grazed in infested areas, place them into quarantine for several days as seed can be carried on the hooves and coats, and in the digestive tracts of livestock. Inspect these quarantine areas regularly to assure no PA-containing plants will start infesting those areas.

**8.2.5 Control of plant and seed movement from urban to agricultural lands and pastures**

Provide educational material to horticulturists and neighbouring property owners to correctly identify PA-containing plants to prevent propagation of unwanted plant species. This information may be supported with national or regional regulations on the propagation, sale and distribution of PA-containing plants. Advise the general public on how to prevent the spread of unwanted, PA-containing plants from urban environments into agricultural and other lands.
